Abstract

Sartobind® Lab units are available with various chromatography membranes that can be used for capture purification and flowthrough polishing of biomolecules.. The macroporous structure allows even large viruses to quickly and easily enter the membrane and to bind to the ligand-rich inner pore surface. This membrane adsorber technology offers a number of benefits compared to conventional chromatography, such as easy handling, high flow rates, minimal mass transfer effects, high capacities, low non-specific adsorption, reduced hardware investment, lower buffer consumption, and easy technology transfer to process-scale devices. This short review highlights publications related to the purification of viruses with Sartobind® IEX Lab units.

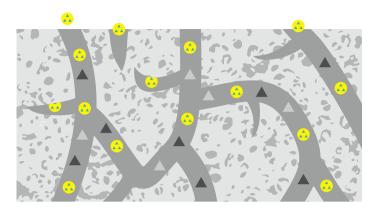

Introduction

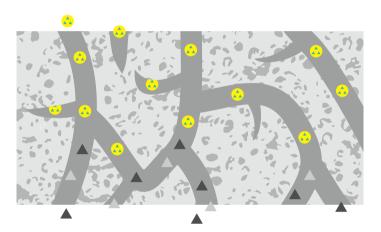

An increasing focus on viruses, virus-like particles and viral vectors for the development of novel vaccines and disease treatments demands efficient purification techniques. Ion exchange chromatography has several advantages over sucrose or caesium chloride density gradient centrifugation, including increased sample capacities, higher virus yields, purity and infectivity, and significantly reduced processing times.

The Sartobind® ion exchange membrane adsorber technology developed by Sartorius offers further benefits over conventional ion exchange chromatography resins. Sartobind® IEX membranes have been incorporated into ready-to-use units that can be operated at much higher flow rates than resin columns, since the larger pores enable convective rather than diffusive movement of the target molecule through the matrix. This results in rapid target capture (adsorption) and elution (desorption), and therefore shorter cycle times. Sartobind® IEX units also have lower buffer requirements thanks to the low bed volumes in comparison to resins. For research and development laboratories, this technology is available within the Vivapure® and Sartobind® Lab product ranges. By design, these provide the ultimate flexibility for sample handling, via centrifugation, syringe, peristaltic pump or liquid chromatography system, using the equipment which is already available to the scientist.

The following examples from peer-reviewed literature illustrate the applicability of Sartobind® IEX Lab to virus purification (Figure 1) in research and development laboratories

Figure 1: Schematic Representation of Virus Purification on Sartobind® Membrane Adsorbers

Purification of Alphaherpesviruses With Sartobind® S Lab

The first ion exchange purification of herpesviruses by Sartobind® IEX Lab was reported by Karger *et al.* in 1998 (Table 1).

Table 1: Purification Conditions for PrV and BHV-1

Sample	Infected cell culture supernatant		
Membrane Adsorber	Sartobind® S Lab with 2.8 mL MV		
Purification Steps	1. Equilibration (20 mM MES, pH 6.2)		
	2. Loading (supernatant diluted 1:2 in MES)		
	3. Washing (25 mL MES)		
	4. Elution (10 mL each of 200, 400, 600 and 1,000 mM KCl in MES)		
	5. Particulate sedimentation (25,000 rpm, 1 h, 4 °C)		
	6. Resuspension (100 μL of TBS (200 mM NaCl, 2.6 mM KCl, 10 mM Tris-HCl pH 7.5, 20 mM MgCl ₂ , 1.8 mM CaCl ₂)		
Flow Rate	10 mL/min		

The results showed that most infectious pseudorabies virus Kaplan strain (PrV-Ka) and lacking glycoprotein gD (PrV-gD-Pass), and bovine herpesvirus 1 (BHV-1) was found after elution with 400 mM KCl in MES buffer (Table 2). More than 85% of the virus was eluted within a single fraction.

Table 2: PrV and BHV-1 Yields After Cation Exchange Chromatography

	PrV-Ka	PrV-gD-Pass	BHV-1
PFU Applied (100%)	$1.4 \times 10^{10} \pm 8 \times 10^{9}$	8.1 × 10 ⁶	1.5 × 10°
PFU Eluted in MES with 400 mM KCI	85.6 ±10.7%*	99%	93%

^{*} Mean ±SD of 3 tests

Densonucleosis Virus Purification by Sartobind® Q | D | S Lab

In 2004, Specht *et al.* purified AeDNV particles with Sartobind® Lab anion and cation exchange units. All three ligands could adsorb the viral particles, depending on the feed pH (Table 3). The results showed no detectable size exclusion effects, indicating that membrane adsorbers are ideally suited to the capture of large viruses.

Table 3: Binding Capacities for Densonucleosis Virus on Sartobind® IEX Lab units with 2.1 mL MV

Ligand	Q	D	S
pН	7.0	7.0	3.5
Virus Charge	Negative	Negative	Positive
Membrane Charge	Positive	Positive	Negative
Protein Capacity	60 mg BSA	45 mg BSA	60 mg lysozyme
Virus Capacity in Water, PFU	>2.79 × 10 ¹⁰	>1.54 × 10°	>3.91 × 10 ⁸
Virus Capacity in Medium, PFU	>1.36 × 10 ¹⁰	>1.36 × 10 ¹⁰	0

Summary

Sartobind® IEX Lab offers an effective means for rapid and convenient purification of viruses. Thanks to the macroporous membrane, viruses can enter the chromatography matrix unhindered. These units are also flexible in operation, due to out-of-the-box compatibility with syringes, peristaltic pumps and liquid chromatography systems. Alternatively, for parallel purification of low volume samples, the centrifugal Vivapure® IEX units are recommended.

For further applications of Sartobind® technology in process-scale virus purification and removal, readers are referred to the related Application Note titled "Virus Purification and Removal: Ion Exchange Chromatography with Sartobind® Membrane Adsorbers".

Note

Literature published up to c.2022 may reference the use of Sartobind® MA, which is a name previously used for the Sartobind® Lab membrane adsorbers. When these products were renamed, there was no change made to fit, form or function. Therefore, results collected and methods established using Sartobind® MA remain valid also for Sartobind® Lab.
